Properties of a Boolean Algebra

1. Operations are *commutative*.
\[
A \cdot B = B \cdot A \\
A + B = B + A
\]

2. Operations are *associative*.
\[
(A \cdot B) \cdot C = A \cdot (B \cdot C) \\
(A + B) + C = A + (B + C)
\]

3. Each operation is *distributive* over the other.
\[
A \cdot (B + C) = (A \cdot B) + (A \cdot C) \\
A + (B \cdot C) = (A + B) \cdot (A + C)
\]

4. There exists an *identity* element for each operation.
\[
+ \text{ Identity } = 0 \quad A + 0 = A \\
\cdot \text{ Identity } = 1 \quad A \cdot 1 = A
\]

5. There exists a *complement* for each element.
\[
\text{Comp:ement of } A = \overline{A} \\
\text{Comp:ement of } 1 = 0 \\
\text{Comp:ement of } 0 = 1
\]

6. There exists an *inverse* for each operation.
\[
A \cdot \overline{A} = 0 \\
A + \overline{A} = 1
\]

7. Each element is *idempotent*.
\[
A \cdot A = A \\
A + A = A
\]

8. The *absorption* property holds for each element.
\[
A \cdot (A + B) = A \\
A + (A \cdot B) = A
\]
**Boolean Algebra**

**DeMorgan's Theorem**

- \( A \ AND \ B = \overline{A} \ OR \overline{B} \)
- \( A \ OR \ B = \overline{A} \ AND \overline{B} \)
Logic Circuits

Combinational or Memoryless Logic Circuits
Function of Current Input Only

Sequential or Memory Logic Circuits
Function of Current Input plus Past Inputs

State Table (Outputs & Next State)
Next State = Present State + Current Input

Moore & Mealy Machines

Moore Machine
Outputs Function of State Only

Mealy Machine
Outputs Function of State and Input

Sequential Machines

Synchronous Sequential Machines
Defined only at discrete times
Controlled by external clock
Uses Flip-Flops to hold state variables between clock pulses

Asynchronous Sequential Machines
Defined for all times
No need for explicit memory
Simpler - Two Implementation Restrictions

Asynchronous Machines

No more than one input variable may change at any on time. State variable must be assigned in such a way that no more than one state variable changes for any possible state changes.

“Simultaneous” Signal Changes
Finite Propagation Times
If 00 > 11 may happen in several ways
00 > 01 > 11 or
00 > 10 > 11
Depends on “who wins the race”
May have “Don’t Care” States
Mealy & Moore Machines

Moore Machine is a finite-state machine whose output values are determined solely by its current state and can be defined as six elements \((S, S_0, \Sigma, \Lambda, T, G)\), consisting of the following:

- a finite set of states \((S)\)
- a start state (also called initial state) \(S_0\) which is an element of \(S\)
- a finite set called the input alphabet \((\Sigma)\)
- a finite set called the output alphabet \((\Lambda)\)
- a transition function \((T : S \times \Sigma \to S)\) mapping a state and the input alphabet to the next state
- an output function \((G : S \to \Lambda)\) mapping each state to the output alphabet.

Mealy Machine output values are determined both by its current state and by the values of its inputs and can be defined as six elements \((S, S_0, \Sigma, \Lambda, T, G)\), consisting of the following:

- a finite set of states \((S)\)
- a start state (also called initial state) \(S_0\) which is an element of \(S\)
- a finite set called the input alphabet \((\Sigma)\)
- a finite set called the output alphabet \((\Lambda)\)
- a transition function \((T : S \times \Sigma \to S)\) mapping a state and the input alphabet to the next state
- an output function \((G : S \times \Sigma \to \Lambda)\) mapping pairs of a state and an input symbol to the corresponding output symbol.

Figure 3-32(b): Transistor ON
12.2 Logic Gates

Logic gates are the building blocks of digital electronics. The fundamental logic gates include the INVERT (NOT), AND, NAND, OR, NOR, exclusive OR (XOR), and exclusive NOR (XNOR) gates. Each of these gates performs a different logical operation. Figure 12.10 provides a description of what each logic gate does and gives a switch and transistor analogy for each gate.

**INVERT (NOT)**

Truth table

<table>
<thead>
<tr>
<th>in</th>
<th>out</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

0 = LOW voltage level
1 = HIGH voltage level

Switch analogy

Lamp (out)

On = 1
Off = 0

Description

A NOT gate or inverter outputs a logic level that's the opposite (complement) of the input logic level.

**AND**

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>out</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

Switch analogy

Lamp (out)

On = 1
Off = 0

Description

The output of an AND gate is HIGH only when both inputs are HIGH.

**NAND**

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>out</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Switch analogy

Lamp (out)

On = 1
Off = 0

Description

Combines the NOT function with an AND gate; output only goes LOW when both inputs are HIGH.

**OR**

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>out</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

Switch analogy

Lamp (out)

On = 1
Off = 0

Description

The output of an OR gate will go HIGH if one or both inputs goes HIGH. The output only goes LOW when both inputs are LOW.

**NOR**

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>out</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Switch analogy

Lamp (out)

On = 1
Off = 0

Description

Combines the NOT function with an OR gate; output goes LOW if one or both inputs are LOW, output goes HIGH when both inputs are LOW.

**Exclusive OR (XOR)**

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>out</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Equivalent circuit

The output of an XOR gate goes HIGH if the inputs are different from each other. XOR gates only come with two inputs.

**Exclusive NOR (XNOR)**

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>out</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

Equivalent circuit

Combines the NOT function with an XOR gate; output goes HIGH if the inputs are the same.
Universal Capability of **NAND** and **NOR** Gates

NAND and NOR gates are referred to as *universal gates* because each alone can be combined together with itself to form all other possible logic gates. The ability to create any logic gate from NAND or NOR gates is obviously a handy feature. For example, if you do not have an XOR IC handy, you can use a single multigate NAND gate (e.g., 74HC00) instead. The figure below shows how to wire NAND or NOR gates together to create equivalent circuits of the various logic gates.

<table>
<thead>
<tr>
<th>Logic gate</th>
<th>NAND equivalent circuit</th>
<th>NOR equivalent circuit</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT</td>
<td>$\overline{A} = \overline{\overline{A}}$</td>
<td>$A \overline{A} = \overline{A}$</td>
</tr>
<tr>

<td>$A \overline{A} = \overline{A}$</td>
</tr>
<tr>
<td>XOR</td>
<td>$A \overline{B} = \overline{A} \overline{B}$</td>
<td>$A \overline{A} = \overline{A}$</td>
</tr>
<tr>
<td>XNOR</td>
<td>$A \overline{B} = \overline{A} \overline{B}$</td>
<td>$A \overline{A} = \overline{A}$</td>
</tr>
</tbody>
</table>
Bubble Pushing

A shortcut method for forming equivalent logic circuits, based on De Morgan’s theorem, is to use what’s called bubble pushing.

AND-OR-INVERT Gates (AOIs)

When a Boolean expression is reduced, the equation that is left over typically will be of one of the following two forms: product-of-sums (POS) or sum-of-products (SOP). A POS expression appears as two or more ORed variables ANDed together with two or more additional ORed variables. An SOP expression appears as two or more ANDed variables ORed together with additional ANDed variables. The figure below shows two circuits that provide the same logic function (they are equivalent), but the circuit to the left is designed to yield a POS expression, while the circuit to the right is designed to yield a SOP expression.

Table made using SOP expression (it's easier than POS)

<table>

FIGURE 12.25

Bubble pushing involves the following tricks: First, change an AND gate to an OR gate or change an OR gate to an AND gate. Second, add inversion bubbles to the inputs and outputs where there were none, while removing the original bubbles. That’s it. You can prove to yourself that this works by examining the corresponding truth tables for the original gate and the bubble-pushed gate, or you can work out the Boolean expressions using De Morgan’s theorem. Figure 12.23 shows examples of bubble pushing.
LOGIC IDENTITIES
1) $A + B = B + A$
2) $AB = BA$
3) $A + (B + C) = (A + B) + C$
4) $A(BC) = (AB)C$
5) $A(B + C) = AB + AC$
6) $(A + B)(C + D) = AC + AD + BC + BD$
7) $1 = 0$
8) $0 = 1$
9) $A \cdot 0 = 0$
10) $A \cdot 1 = A$
11) $A + 0 = A$
12) $A + 1 = 1$
13) $A \cdot A = A$
14) $AA = A$
15) $A + A = 1$
16) $A \cdot A = 0$
17) $A \cdot A = 0$
18) $A + B = A \overline{B}$
19) $AB = A + B$
20) $A + AB = A + B$
21) $A + AB = A + B$
22) $A \oplus B = \overline{AB} + A\overline{B} = (A + B)(\overline{A}\overline{B})$
23) $A \oplus B = AB + A\overline{B}$

Digital Logic Signal Levels and State Variables

Simple Positive Logic

Define "Lo" = State "0" = 0; i.e., "near 0 volts, or maybe +0.7V, or less than +2.1V, etc."
Define "Hi" = State "1" = 1; i.e., "near Vcc, say +5V, or greater than +3.9V, etc. for TTL; or +15V, or greater than +13.1V, etc. for CMOS."

Remember these are arbitrary definitions.
Notice however, that State "1" is more positive than State "0". With this in mind, we can even define "Hi" = State "1" = 1 = 0 volts, and "Lo" = State "0" = 0 = -5 volts.
We still have State "1" more positive than State "0".
And Boolean Algebra doesn't care!

Simple Negative Logic

Try reversing things, such that State "1" is more negative than State "0"; i.e.,
State "1" = 0 volts, and
State "0" = +5 volts, or even
State "1" = -5 volts, and
State "0" = 0 volts
In both cases, State "1" is more negative than State "0".

Note: Positive AND Logic = Negative OR Logic
Positive OR Logic = Negative AND Logic

DeMorgan's Law

\[
\overline{A \cdot B} = \overline{A} + \overline{B} \quad \quad \overline{A + B} = \overline{A} \cdot \overline{B}
\]

Positive Logic \( A \cdot B \) = Negative Logic \( \overline{\overline{A} + \overline{B}} \)

Positive Logic \( A + B \) = Negative Logic \( \overline{A \cdot \overline{B}} \)
Making Sense of SR Flip Flop Seemingly Contradictory Explanations

SR Flip Flop
Unfortunately, there is no consistency in describing the operation of SR Flip Flops (Set Reset); in fact, many of us even refer to them as RS Flip Flops. However, one property description is pretty much universal:

Set S implies \( Q = 1 \)
Reset R implies \( Q = 0 \)

Adding even more to the confusion, is an error in our BME 460 Paul Scherz textbook, *Practical Electronics for Inventors*, 2ed, page 682, Figure 12-70, Cross NAND SR Flip Flop; the outputs \( Q \) and \( \overline{Q} \) are reversed. \( Q \) should be associated with the S input NAND gate and \( \overline{Q} \) should be associated with the R input NAND gate.

Be careful, don't confuse yourself when using other resources; some authors associate \( Q \) and \( \overline{Q} \) with S & R respectively, other authors reverse the association. And then there is the confusion with respect to NOR SR Flip Flops, NAND SR Flip Flops, and inverted inputs to both NOR and NAND Flip Flops. For our BME 460 purposes, the following concepts apply:

Set S implies \( Q = 1 \)
Reset R implies \( Q = 0 \)

Not Allowed

NOR Gates \( S = 1 \) and \( R = 1 \)
NAND Gates \( S = 0 \) and \( R = 0 \)

If provisions for a clock pulse are not available, the circuit is known as an asynchronous flip flop.

Triggered or T Flip Flops
If the S and R inputs are gated with a clock pulse, the circuit is known as a synchronous flip flop. If gated by a NAND, the S and R inputs are only enabled when the clock pulse is high. When the clock is low, the inputs are disabled and the flip flop is placed in the Hold mode.

Latched Data or D Flip Flops (Single Input Device)
Invert the S input and apply to the R input:

if \( S = 0 \) then \( R = 1 \)
if \( S = 0 \) then \( R = 0 \)
but never \( S = R \)

Rename S as D:

\[
\begin{array}{c|c|c|c|c}
\hline
D & S & R & Q \\
\hline
0 & 0 & 1 & 0 \text{(Reset)} \\
1 & 1 & 0 & 1 \text{(Set)} \\
\hline
\end{array}
\]

Each change in the input data toggles a change in the output.

J K Master-Slave Flip Flop
Inputs: J, K, Set, Clear, Clock
Outputs: \( Q \), \( \overline{Q} \)

Trailing Edge Triggered Flip Flop
Master triggers on the clock up-tick (slave inactive)
Slave follows master on the clock down-tick

\[
\begin{array}{c|c|c|c}
\hline
\text{Control} & Q & \overline{Q} \\
\hline
\text{Set} & 1 \\
\text{Clear} & 0 \\
\hline
\end{array}
\]

\[
\begin{array}{c|c|c|c}
\hline
\text{Input} & Q & \overline{Q} \\
\hline
0 0 & Q \text{ Hold} \\
0 1 & 0 \text{ Reset} \\
1 0 & 1 \text{ Set} \\
1 1 & \overline{Q} \text{ Toggle} \\
\hline
\end{array}
\]
555 Astable Multivibrator Characteristics

The following computational formulas apply to the 555 configuration shown above.

On-Time  \( t_1 = 0.69 \left( R_1 + R_2 \right) C \)

Off-Time  \( t_1 = 0.69 \left( R_2 \right) C \)

Period  \( t_1 + t_{1h} = 0.69 \left( R_1 + 2R_2 \right) C \)

Frequency  \( = \frac{1}{\text{Period}} = \frac{1.44}{\left( R_1 + 2R_2 \right) C} \)

Duty Cycle  \( = \frac{t_{1h}}{t_1 + t_{1h}} = \frac{R_1 + R_2}{R_1 + 2R_2} \)
RS Flip Flop Truth Tables

In order to eliminate ambiguity and to achieve some sense of continuity, we will follow the convention:
Set implies $Q = 1$.
Reset implies $Q = 0$.

As you can see, there is consistency for Set means $Q=1$ and Reset means $Q=0$; but there can be confusion trying to decide whether-or-not S & R are 0 or 1 depending on the type of gates (NOR or NAND).
If inverted S & R inputs are used with the NAND gates, then S=1 is the Set input and R=1 is the Reset input; which is the same as the NOR gates implementation.
Rectangular Wave & Square Wave Generators (Op-Amp Schmitt Triggers & 555 Timers)

Figure 16-15: Square-wave generator

Figure 16-17: The 555 timer connected as a rectangular waveform generator

Electronic Devices: a design approach, Ali Aminian & Marian Kazimierczuk, 2004
SQUARE-WAVE GENERATOR

Recall that the output of the Schmitt trigger, which was introduced in Chapter 11 as a bi-reference level comparator, is a square wave with $\pm V_{o(p)} = \pm V_{sat}$ of the op-amp. With the addition of a capacitor $C$ and a feedback resistor $R$, as shown in Figure 16-15(a), the need for an input signal is eliminated and the output frequency can also be controlled by proper selection of the $R$ and $C$.

![Circuit diagram](image)

(a) Circuit diagram

![Output waveform](image)

(b) Output waveform

Figure 16-15: Square-wave generator

Referring to Equations 11-7 and 11-8, the upper and lower threshold voltages ($V_{UT}$ & $V_{LT}$) or $(\pm V_{th})$ can be written in one equation as follows:

$$\pm V_{th} = \pm V_{sat} \frac{R_2}{R_1 + R_2}$$  \hspace{1cm} (16-64)

It can be shown, with some considerable algebraic effort, that the period of the output waveform is as follows:

$$T = 2RC \ln \left( \frac{2R_2}{R_1} + 1 \right)$$  \hspace{1cm} (16-65)

$$f_o = \frac{1}{T} = \frac{1}{2RC \ln(2R_2 / R_1 + 1)}$$  \hspace{1cm} (16-66)

However, if we select $R_1$ and $R_2$ such that $(1 + 2R_2/R_1) = 2.178$ (the natural log base), then $\ln(1 + 2R_2/R_1)$ will equal unity.

$$\frac{2R_2}{R_1} + 1 = 2.718$$  \hspace{1cm} (16-67)

$$2R_2 = 1.718R_1$$  \hspace{1cm} (16-68)

$$R_2 = 0.859R_1$$  \hspace{1cm} (16-69)

Hence, the output frequency is a function of $R$ and $C$ only, and its equation simplifies as follows:

$$f_o = \frac{1}{2RC}$$  \hspace{1cm} (16-70)

Electronic Devices: a design approach, Ali Aminian & Marian Kazimierczuk, 2004
16.8 THE 555 TIMER

The 555 timer is a popular 8-pin integrated circuit (IC), which may be used in many applications including rectangular waveform generation. Figure 16-17 shows the common configuration of the 555 timer as it is connected to produce a rectangular waveform.

![Circuit Diagram](image)

(a) Circuit diagram

![Output Waveform](image)

(b) Output waveform

**Figure 16-17**: The 555 timer connected as a rectangular waveform generator

The time duration for which the output is high \((t_H)\) is given by the following equation:

\[
t_H = 0.69(R_1 + R_2)C \tag{16-71}
\]

The time duration for which the output is low \((t_L)\) is given by the following equation:

\[
t_L = 0.69R_2C \tag{16-72}
\]

Therefore, the period and frequency of the waveform are as follows:

\[
T = t_H + t_L = 0.69(R_1 + 2R_2)C \tag{16-73}
\]

\[
f = \frac{1}{T} = \frac{1}{0.69(R_1 + 2R_2)C} \tag{16-74}
\]

For a rectangular waveform, the ratio of the pulse duration \((t_H)\) to the period \(T\) is referred to as the duty cycle \((d)\) of the waveform. A square wave is a rectangular waveform with \(d = 0.5\) or 50% duty cycle. Examining the equations for \(t_H\) and \(t_L\), we notice that it would not be possible to produce a square wave with the circuit of Figure 16-16. However, there is a simple solution for this problem, and that is to connect a diode across the \(R_2\) and let \(R_1 = R_2 = R\), as illustrated in Figure 16-18(a).

Electronic Devices: a design approach, Ali Aminian & Marian Kazimierczuk, 2004
Figure 16-18: The 555 timer connected as a square-wave generator

When the output is high, the diode is forward-biased, shorting out $R_2$; hence,

$$t_H = 0.69(R_1)C = 0.69RC$$  \hspace{1cm} (16-75)

When the output is low, the diode is unbiased, behaving like an open-circuit; hence,

$$t_L = 0.69(R_2)C = 0.69RC$$  \hspace{1cm} (16-76)

$$T = t_H + t_L = 0.69RC + 0.69RC = 1.38RC$$  \hspace{1cm} (16-77)

$$f_o = \frac{1}{T} = \frac{1}{1.38RC}$$  \hspace{1cm} (16-78)

$$d = \frac{t_H}{T} = \frac{0.69RC}{1.38RC} = 0.5$$  \hspace{1cm} (16-79)

In order to produce a rectangular waveform with a duty cycle less than 50% ($t_H < t_L$), we can pick $R_2$ larger than $R_1$, as required. However, the practical solution is to split $R_2$ into a series combination of a fixed resistor and a potentiometer, so that $R_2$ can be adjusted for a desired duty cycle.

Figure 16-19: Rectangular waveform generator of Design Example 16-6

Electronic Devices: a design approach, Ali Aminian & Marian Kazimierczuk, 2004
NAND Gate Equivalent Circuits

Two-input (X & Y) with one-output (F) logic gate circuits can be defined by a total of 16 functions.
